

Question 1

What is the bound charge distribution of an infinitely long uniformly polarized equilateral triangle whose polarization is \mathbf{P} . What is the total bound charge? What is the far field electric field produced by the triangle?

Intuitively, the charge distribution will be positive pushed up, and negative pushed down. The bottom plane of the triangle will collect the negative charges however, the top two plane will accumulate half the positive charges each. The mathematical representation for the surface bound charge density is:

$$\sigma_b = P \cdot \hat{n}$$

For this triangular solid there are three normal vectors to solve for. Measuring from $\theta = 0$ pointing straight up, the three normal vectors are: $\hat{n}_1: \theta_1 = \frac{-\pi}{3}$, $\hat{n}_2:$

$\theta_2 = \frac{\pi}{3}$, and \hat{n}_3 : $\theta_3 = \pi$.

Solving for the surface bound charge densities:

$$\begin{aligned}\sigma_{b1} &= P \cdot \hat{n}_1 = P \cos\left(\frac{-\pi}{3}\right) \\ &= \frac{P}{2} \\ \sigma_{b2} &= P \cdot \hat{n}_2 = P \cos\left(\frac{\pi}{3}\right) \\ &= \frac{P}{2} \\ \sigma_{b3} &= P \cdot \hat{n}_3 = P \cos(\pi) \\ &= -P\end{aligned}$$

The volume charge density is equal to the negative divergence of the polarization, and the divergence of a uniform polarization is 0, so ρ_b for this material is 0.

At far distances, the minor accumulations of charge on the top and the larger accumulation of charge down below will look like a dipole. Assuming this material extends infinitely into the page and infinitely out of the page, the electric field will only change as a function of theta and r, the distance away.

Another assumption to solve the field, I am going to assume that the location of the surface charges will be at the midpoints of the faces of the triangle, and the middle of the triangle is the origin. This locates σ_1 @ (x,z) $\left(\frac{-a}{4}, \frac{\sqrt{3}a}{12}\right)$, σ_2 @ $\left(\frac{a}{4}, \frac{\sqrt{3}a}{12}\right)$, σ_3 @ $\left(0, \frac{-\sqrt{3}a}{6}\right)$.

Question 2
